Aurevix — Co-Founder Briefing

Plain-language brief on what we changed, why the product is defensible, and what every feature does for the business. Written to be readable in one sitting and to arm you for investor and partner questions.

TL;DR (read this if you read nothing else)

Aurevix turns a phone video of a task into controller-ready robot code, in hours, for six robot brands, with no engineer. We just shipped a round of UI changes that fix the product's biggest credibility gaps — most importantly, "confidence %" is now a **defined, safety-gated "deploy readiness" score**, and our **ISO safety posture** and **cross-vendor portability** are now visible. Our defensibility is **not** the idea (others have "no-code robot teaching") — it's three things that compound: a **vendor-neutral abstraction layer** that the robot makers themselves won't build, **switching costs** from owning the customer's task library and validation history, and a **demonstration-data flywheel** (reinforced by KineTrace) that gets better the more tasks are taught. Our sharpest wedge against the best-funded competitor (Wandelbots, $120M+) is simple: **they need a physical TracePen device; we need a phone.**

Part A — What we changed, and why it matters commercially

You implemented most of the audit recommendations. Here is what each fix actually buys us:

What changed	Before → After	Why it matters for sales
"Confidence %" is now defined	A bare "68%" with no meaning → **"Deploy readiness"** with explicit gates: **below 80% blocked, 80–89% needs simulation review, 90%+ ready for supervised deployment**	This was the single most damaging trust gap. A buyer staring at "68% confidence" on a *welding* skill used to feel fear. Now they see a system that *gates risk for them*. We turned a scary number into a reason to trust us.
Safety posture is visible	No compliance signals → **"Safety-aware: ISO 10218 and ISO/TS 15066 referenced"** and **"Human verified: deployment remains gated for review"**	For anyone responsible for a robot that can injure a person, safety credibility *is* the authority signal. This is now answered on the screen, not buried.
Cross-vendor portability is named	Hidden → **"Cross-vendor: UR, ABB, FANUC and ROS 2 workflows"** + the Automation Passport ("taught on UR10e → re-planned for ABB GoFa")	This is our biggest structural advantage. It was previously invisible. Now it's a headline.
The hero is the magic moment	Vague "Teach a robot" on top → **"Run the 30-second workflow"** is the above-the-fold hero	The strongest, most specific call to action is now where motivation is highest.
Nav renamed for clarity	"Skills / Skill Library / Task Library" (unpredictable) → **"My Skills / Skill Templates / Task Records"**	New users can now predict what's behind each item instead of guessing.
Honest data messaging	"persisted to the local workspace" (alarming) → **"Demo updates are stored in this browser. Production**	Removes a contradiction that made us look untrustworthy mid-demo.

What changed	Before → After	Why it matters for sales
	workspaces use durable cloud records."	
Internal labels removed	"SALES ARTIFACT" / "DEMO RESILIENCE" (fourth-wall breaks) → **"YOUR ROI" / "Demo data & recovery"**	We no longer tell the prospect, in our own words, that they're looking at a sales prop.
Units fixed	Said "imperial" but showed metric → now correctly **"Metric (mm, kg, °C)"**	Small bug, big signal: a precision tool can't get its own units wrong.

Net effect: the console now reads as *trustworthy and intentional* rather than *impressive-but-leaky*. For a product whose entire pitch rests on "trust us with your robots," that shift is worth more than any new feature.

Part B — Why Aurevix is defensible (the honest version)

There is no single magic moat. There are **four layers**, and they differ in how real they are *today* versus how real they become *with scale*. Be precise about which is which — investors and sophisticated partners will test you on it.

Layer 1 — Structural moats (defensible by design, true today)

1. The vendor-neutral abstraction layer ("the Switzerland position"). Aurevix sits *above* the robot makers — Universal Robots, ABB, FANUC, KUKA, Techman, Yaskawa — as a single teaching-and-portability layer. A task taught once can be re-planned and re-exported for a *different brand* (we already show UR10e → ABB GoFa). This is defensible for a structural reason: **the OEMs will never build this themselves.** Each one wants you locked into *their* pendant, *their* code, *their* ecosystem. A cross-vendor layer is against their interest, which leaves the position open for an independent — us. It's also genuinely hard engineering (six brands' kinematics, I/O, and code generation), which raises the barrier for new entrants.

2. Switching costs / system-of-record lock-in. Once a manufacturer's taught tasks, workcell configurations, validation history, and execution records live in Aurevix, leaving means re-teaching everything from zero. The "Task Records / Automation Passport" *is* the lock-in: the longer a customer uses us, the more their operational memory lives in our format. This compounds quietly and is one of the most durable B2B moats there is.

Layer 2 — Compounding moats (get stronger as we grow)

3. The demonstration-data flywheel. Every video taught is a data point about how humans-intend-tasks → robot-actions. More tasks → better intent extraction → better skills → more customers → more tasks. **KineTrace** (our annotation product for robot-learning datasets) plugs directly into this — it's both a revenue line and a data engine. This is potentially our strongest *long-term* moat, **but only if** (a) the data is allowed to compound across customers, and (b) we have the rights to use it. That requires a deliberate data-rights strategy (see watch-outs). Treat it as a moat we are *building*, not one we already have.

4. The validation / deploy-readiness corpus. Every executed cycle feeds the deploy-readiness score. Over time, Aurevix accumulates a track record of "this kind of task, on this robot, with this gripper, performs like this." That historical confidence data is proprietary, hard to replicate, and directly powers the safety story. It gets more valuable with every cycle run.

Layer 3 — Earned moats (built over time, not given)

5. The safety-and-trust reputation. In a domain where a bad output can hurt someone, being *the trusted option* is a moat — but it's earned through track record, not declared. The deploy-readiness gating, the "human verified" framing, and the ISO references are the right scaffolding. Protect this reputation obsessively; it's slow to build and instant to lose.

Layer 4 — Go-to-market edges (not moats, but real advantages)

- **Video-only, no special hardware.** The closest funded competitor, Wandelbots, requires a physical "TracePen" you trace the path with. We need a phone. That's lower friction, lower cost, and a cleaner story.
- **Outcome-aligned pricing.** Flexible pricing with no per-task fees (and an outcome-based option) attacks the exact pain — "the integrator tax" — and lowers adoption risk for the customer.
- **Speed as the wedge.** "Hours, not weeks" / "90% less programming time" lands the deal; the moats above keep them.

Honest watch-outs (the questions you *will* be asked)

- **We're early; competitors are funded.** Wandelbots has raised ~$120M+; Micropsi, Augmentus, and others are in the space. The *idea* of no-code teaching isn't ours to own — our edge is the video-only approach, the cross-vendor layer, and **execution + data**, not novelty. Frame it that way.
- **The data flywheel needs a rights strategy.** Customers may not want their task data training models that could help competitors. Decide early: per-customer isolation vs. anonymized cross-customer learning, and get the contractual rights. Without this, the flywheel is weaker than the pitch.
- **Cross-vendor support is a treadmill.** Every new robot/gripper/format is ongoing cost. It's a moat *and* a burden — budget for it.
- **Intent-extraction accuracy on novel/complex tasks is the core technical risk.** Deploy-readiness gating manages the *risk*; it doesn't fix the *model*. Underlying accuracy is what ultimately wins. Keep that honest internally.
- **Liability surface.** We generate code for machines that can injure people. The human-verified gate is non-negotiable, and so is being careful in copy never to imply we replace the customer's safety process (the site already does this well — keep it).

Part C — Competitive position in one page

	Aurevix	**Wandelbots (closest funded peer)**	**Traditional integrator / teach pendant**
Input method	**Phone video** — no hardware	Physical **TracePen** device, traced by hand	Teach pendant + custom code
What it learns	**Task intent** (pick/orient/place/wait/signal), then re-plans for the robot	Recorded path / motion	Manually programmed waypoints
Hardware needed	None	TracePen (proprietary)	Pendant + engineer
Multi-brand	UR, ABB, FANUC, KUKA, Techman, Yaskawa	Multi-brand	Brand-specific

	Aurevix	Wandelbots (closest funded peer)	Traditional integrator / teach pendant
Who can do it	Existing factory worker	Trained operator	Specialist / integrator
Cost model	Flexible, no per-task fee	License-based	5*K*–15K **per task change**

The one-line wedge: "*Wandelbots needs a pen. The integrator needs a calendar slot and an invoice. Aurevix needs a video.*"

Part D — What every feature does, and why it's there (intentionality)

For each: what it is → why we built it that way → what it buys the business.

Teach from video (the core engine). Record a task on a phone; Aurevix extracts intent and builds a robot-specific plan. *Intentional choice:* we deliberately do **not** copy the human's motion — we extract intent and re-plan for the robot's kinematics. *Business value:* this is the wedge that lands every deal and the thing competitors with hardware can't match on friction. It also expands our buyer from "robotics engineers" to "any factory worker," which massively widens the market.

The guided workflow that "hides robot logic until you need to edit it" (with an "Edit advanced logic" escape hatch). *Intentional choice:* progressive disclosure — simple by default, powerful on demand. *Business value:* keeps the experience approachable for the non-expert buyer (who signs the deal) while not alienating the integrator (who validates it). One product serves both audiences.

Deploy readiness scoring with gates (below 80% blocked / 80–89% sim review / 90%+ supervised deploy). *Intentional choice:* make the AI an *assistant with guardrails*, not an autopilot. *Business value:* this is our trust and safety story made concrete. It's the answer to "how do I know it's safe to run?" — and a differentiator most "no-code" tools don't articulate.

Multi-step sequencing with conditional logic, signal-waits, and machine-tending. Chain pick → orient → place → wait-for-signal → release, with IF conditions. *Business value:* moves us beyond toy pick-and-place into *real production tasks*, which is where the budget is. This is what makes us credible to a plant, not just a demo.

Tool-changer support (auto dock/undock). Configure tool stations once; Aurevix inserts dock/undock moves wherever a skill needs a different end-effector (gripper → vacuum → screwdriver). *Business value:* multi-tool cells are high-value, sticky deployments. Owning this complexity deepens lock-in and justifies premium tiers.

Gripper breadth (pneumatic, electric servo, vacuum). *Business value:* "we support the grippers factories actually use" removes a common disqualifier and widens addressable cells.

Workcell setup (gripper + I/O mapping, configure once). *Intentional choice:* configure the cell once, reuse across all generated code. *Business value:* correctness + reuse = fewer errors and faster subsequent tasks, which drives the "hours not weeks" promise on task #2 onward.

Simulation before deployment (3D replay). *Business value:* "review before hardware moves" is a direct risk-reducer that safety-conscious buyers require. It's table stakes for trust and we have it built in.

Code export (URScript, RAPID, ROS 2 Python, FANUC TP/Karel, PDF report). *Intentional choice:* native controller code, not a black box. *Business value:* paradoxically, *giving* them portable code reduces "lock-in fear" at purchase — while the *task library and validation history* create the real switching cost. Best of both: low fear to adopt, high cost to leave.

Automation Passport / Task Records (system-of-record). The portable, re-plannable record of every taught task. *Business value:* **this is the moat made visible.** It's the cross-vendor portability artifact *and* the lock-in *and* the operational memory. Name it, market it, protect it.

ROI Calculator (shareable PDF / link / email). *Intentional choice:* arm the internal champion. *Business value:* B2B deals are won by the champion selling *internally*. A downloadable ROI artifact lets them make our case to their boss when we're not in the room. It shortens the sales cycle.

Execution history + fleet view. *Business value:* operational confidence and proof-of-value over time (uptime, cycles, success rates) — the data that justifies renewal and expansion.

Outcome-based / value-based billing option. Bill on verified successful cycles, never retroactive, no charge for missing/estimated outcomes. *Intentional choice:* align our revenue with their success. *Business value:* lowers the buyer's adoption risk ("you only pay when it works") and differentiates us from license-heavy competitors. It's a trust-building GTM lever as much as a pricing one.

Safe Demo Mode. Deterministic, cached demo that survives flaky connectivity. *Business value:* a sales tool — the demo never breaks in front of a prospect. Unglamorous but it protects every top-of-funnel moment.

The throughline (one paragraph to memorize)

Aurevix's strategy is to be the **independent software layer that makes any factory's robots as easy to retask as showing someone a video** — and to make that independence *sticky*. The wedge is video-only teaching (no hardware, no engineer). The depth (multi-step, tool-changer, safety gating) makes us credible for real production. The moat is structural (cross-vendor, which the OEMs won't build) plus accumulating (the task library, the validation history, the demonstration data + KineTrace). We win the deal on **speed and ownership**, and we keep the customer because **their automation memory lives in us, in a format that travels across every robot brand they own.**
